Adobe Photoshop cc2018, Adobe a 6.0. We can help you to activate your software very fast. We are a valuable software provider. Activate - Unlimited Download - 90 days[Incidence of dental caries among schoolchildren living in the city of São Paulo, Brazil, from 1995 to 2000]. To determine the frequency of dental caries in schoolchildren. A descriptive study of dental caries was carried out with a sample of schoolchildren from the public and private schools in the city of São Paulo, Brazil, using the data from the Brazilian National School-based Surveillance of Dental Caries of schoolchildren. The data was obtained from

the annual report of 1995 to 2000, by grouping the children according to gender and age. The data were analyzed using the statistical analysis program Minitab v10 and adjusted by the non-parametric test of the Kruskal-Wallis, followed by Dunn's post test for pairwise comparison, the Spearman correlation test, and the chi-square test. The sample comprised 20,961 children in

3,354 classes, with a total of 69,932 teeth (32,503 maxillary and 36,429 mandibular). Of the children who were present at school on the day the examination was performed, only 55% presented for the examination. The results indicated that 52% of the children had caries in their primary dentition, whereas 34% had caries in their permanent dentition. The study showed that the prevalence of dental caries increased with age, being highest in the 11- to 13-year age group and in the primary dentition.

There was a significant correlation between the occurrence of dental caries and the socioeconomic status of the family, with the

incidence of caries in the poorest families being the highest. This study showed that the frequency of dental caries in the primary dentition was higher than that in the permanent dentition, and this was especially noticeable among schoolchildren who presented for their first dental visit, in the 11- to 13-year age group, with high family income, or who presented with a healthy appearance.
